

TEEN PREGNANCY IN ARIZONA, 2006

FACT SHEET

OVERVIEW

- In 2006, 14,676 females age 15 to 19 became pregnant in Arizona.
- 12,746 of these pregnancies resulted in live births (86.8%), 1,850 pregnancies were aborted (12.6%) and 80 pregnancies resulted in fetal deaths (.6%).
- The number of pregnancies that resulted in live births in Arizona (86.8%) is notably higher than the national average (56.1%).

Teenage Pregnancy Outcomes

Note: U.S. data is from 2002 and provided by the National Center for Health Care Statistics' report: "Recent Trends in Teenage Pregnancy in the United States, 1990-2002."

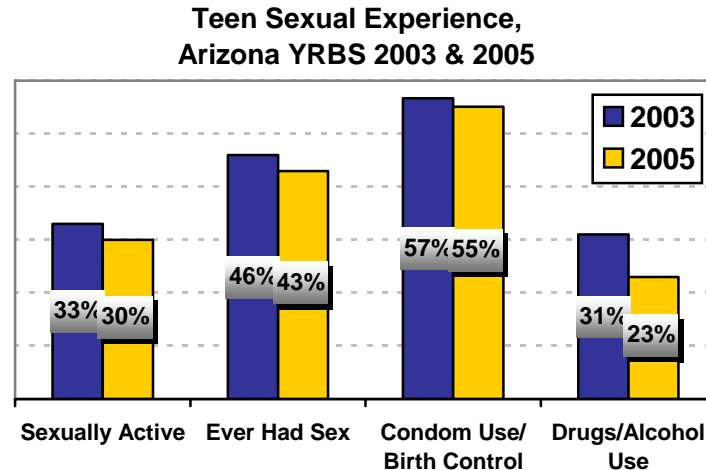

- Arizona's teenage pregnancy rate in 2006 was 68.7 per 1,000 females age 15 to 19, which is higher than the previous year's (2005) rate of 65.6 per 1,000 females.
- Despite the recent increase, the teenage pregnancy rate has actually been on the decline over the past decade; in fact, it has decreased by 24.8% below 1996 levels.
- The majority of the decline in teen pregnancy rates (as much as 86%) is attributed to improved contraceptive use among sexually active teens and higher proportions of teens choosing to delay sexual activity.¹

¹ Santelli J et al. Explaining recent declines in adolescent pregnancy in the United States: the contribution of abstinence and improved contraceptive use. American Journal of Public Health 2007; 97: 3.

WHY ARE RATES DECLINING SINCE THE 1990s?

- Nationally, the rate of teens using condoms and contraceptives has increased. National statistics indicate that males and females whose first intercourse occurred in the mid-1990s through 2002 are much more likely to be protected at first intercourse than their counterparts having first sex before 1990. About 3 out of 4 teens used a method of contraception at their first intercourse. About 91% of males and 83% of females used a method last time they had intercourse.²
- The percentage of teens having sex has also dropped. In the United States, the percentage of males age 15-19 who ever had sexual intercourse declined between 1995 and 2005 from 54% to 47%. Teenagers are also delaying sex until later in life. In 2002, 13% of never-married female teens had had sex before age 15 compared to 19% in 1995; 15% of males had done so compared to 21% in 1995.³

- Results from the 2005 Arizona Youth Risk Behavior Survey⁴ show that both the percentage of students who have ever had sex and the percentage of students who are currently sexually active have decreased since 2003.

- A larger decrease was observed in the percentage of students who drank alcohol or used drugs prior to sexual intercourse; however the difference was not statistically significant. And while the percentage of students who reported using a condom or birth control decreased slightly from the 2003 survey, the difference was not large enough to be statistically significant.

DEMOGRAPHIC ANALYSIS

Race/Ethnicity

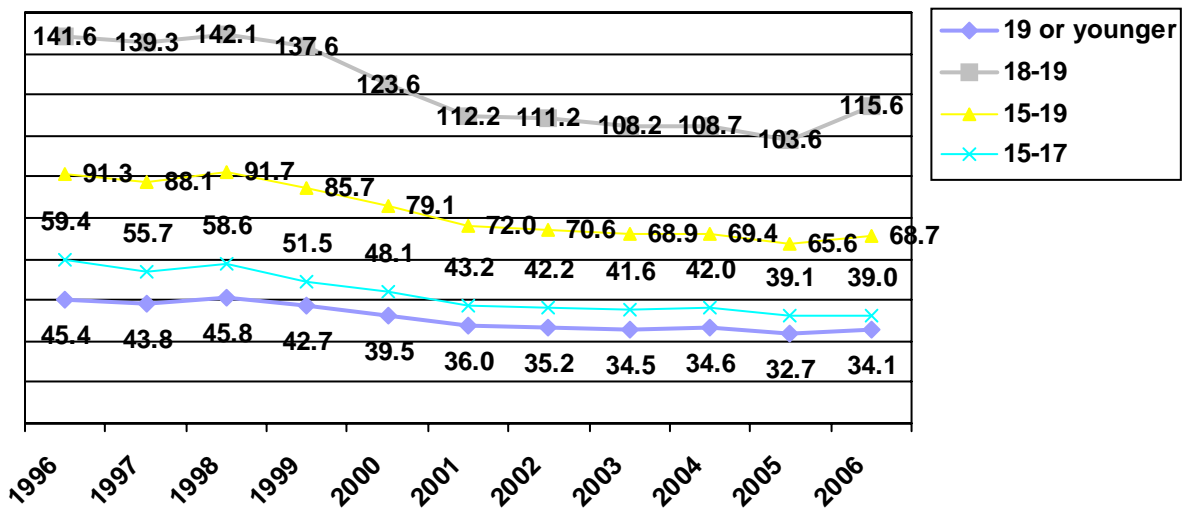

- In 2006, Hispanics or Latinos continued to have the highest teen pregnancy rate (56.0 per 1,000 females aged 19 and younger), followed by American Indian (36.2 per 1,000), African American (32.6 per 1,000), White, Not Hispanic (18.9 per 1,000) and Asian or Pacific Islander (12.9 per 1,000).
- The teen pregnancy rate for White, Not Hispanic females showed a sharp increase over the past year, from 15.8 per 1,000 females age 19 or younger in 2005 to 18.9 per 1,000 females in 2006.
- The teen pregnancy rate for Hispanic or Latinos stayed relatively stagnant over the past year while other groups showed a sharp decline. The largest decrease was for African Americans, whose pregnancy rate dropped from 43.5 per 1,000 females age 19 or younger in 2005 to 32.6 per 1,000 females in 2006 – the lowest level recorded over the past decade.

Age Groups

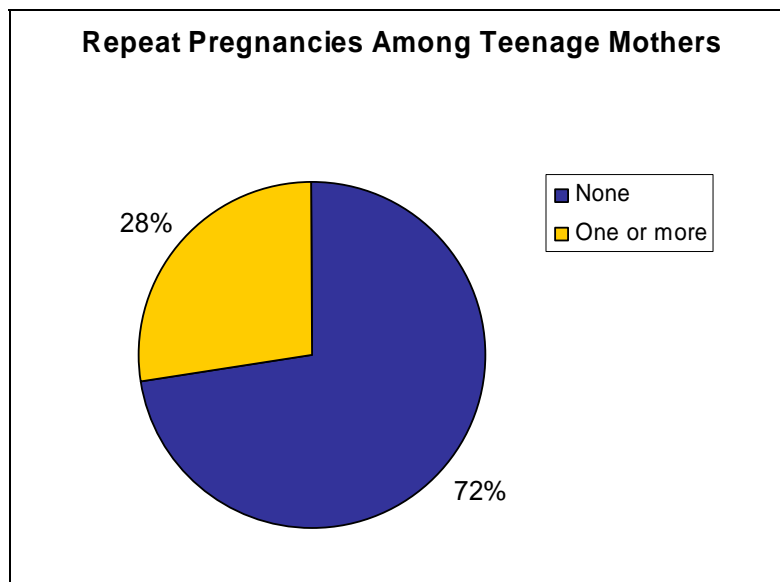

- Nearly two-thirds of all teen pregnancies (64.2%) occur among 18 to 19 year-olds; less than 2 percent (1.6%) occur among mothers that are 15 years or younger .
- The teen pregnancy rate for 18 to 19 year olds increased from 103.6 per 1,000 females in 2005 to 115.6 per 1,000 females in 2006 – its highest level since 2000.
- The teen pregnancy rate for all other age groups either stayed stagnant or showed a slight increase from 2005 to 2006.

**Teenage Pregnancy Rate by Age Group,
Arizona 1996-2006**

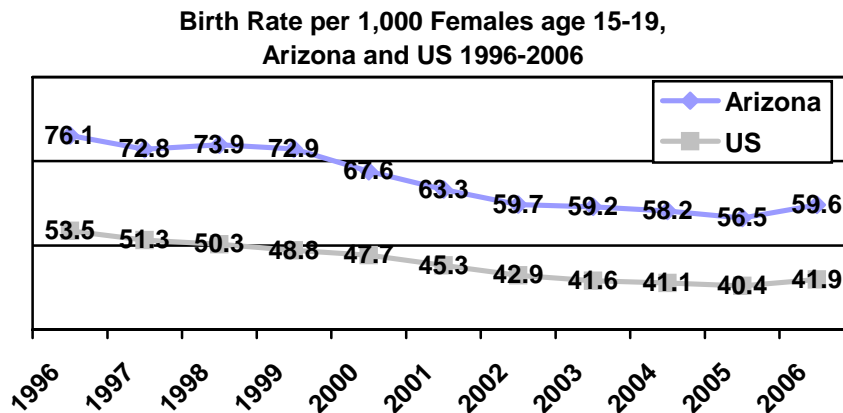

SUBSEQUENT BIRTHS TO TEENS

- 3,511 out of 12,746 or more than 1 in 4 teenage mothers (age 15-19) who gave birth in 2006 had experienced previous pregnancies (see chart below).
- The rate of subsequent births to teenage mothers has remained relatively constant over the past decade (fluctuating between 28 and 30 percent; data not shown).

TEENAGE BIRTHRATE COMPARISON

- In 2006, Arizona experienced its first increase in the teen birth rate⁵ in nearly a decade, from 56.5 per 1,000 females age 15-19 in 2005 to 59.6 in 2006. However, the teen birth rate has actually dropped by 21.7 percent since 1996.
- Arizona's teen birth rate is consistently higher than the nation's, as displayed in the figure below. In 2006, Arizona's teen birth rate was 42.2% higher than that of the nation's⁶.

Note: U.S. data from provided by the National Campaign to Prevent Teen Pregnancy's report "Teen Birth Rates in the United States" (available at teenpregnancy.org).

WHAT ARE THE CONSEQUENCES OF TEEN PREGNANCY?

- Research shows a strong connection between teen pregnancy and a number of negative consequences for mothers, fathers, and their children.⁶
 - Teen mothers are less likely to complete high school: only one-third receive a high school diploma and a mere 1.5% have a college degree by age 30.
 - Teen mothers are more likely to end up on welfare: nearly 80 percent of unmarried teen mothers end up on welfare.⁷
 - The children of teenage mothers have lower birth weights, are more likely to perform poorly in school, and are at greater risk of abuse and neglect.
 - The sons of teen mothers are 13 percent more likely to end up in prison while teen daughters are 22 percent more likely to become teen mothers themselves.

⁵ The teen birth rate one of three general indicators of teenage pregnancy – the other two being spontaneous terminations of pregnancies (fetal deaths or stillbirths) and induced terminations of pregnancies (abortions) – and used here for comparative purposes with national trends.

WHAT ARE THE PUBLIC HEALTH COSTS ASSOCIATED TEEN PREGNANCY?

- An analysis from the National Campaign to Prevent Teen Pregnancy shows that teen childbearing (teens 19 and younger) in Arizona cost taxpayers (federal, state, and local) at least \$252 million in 2004.
- Most of the costs of teen childbearing are associated with negative consequences for the *children* of teen mothers. In Arizona, in 2004, annual taxpayer costs associated with children born to teen mothers included: \$48 million for public health care (Medicaid and SCHIP); \$32 million for child welfare; \$43 million for incarceration; and \$88 million in lost tax revenue, due to decreased earnings and spending.
- The costs of childbearing are greatest for younger teens. In Arizona, the average annual cost associated with a child born to a mother 17 and younger is \$3,364.
- Between 1991 and 2004 there have been more than 158,300 teen births in Arizona, costing taxpayers a total of \$3.4 billion over that period.
- Because the teen birth rate in Arizona declined 25% between 1991 and 2004, an estimated \$101 million (in taxpayer's dollars) was saved in 2004 alone.
- Public health insurance (AHCCCS & IHS) paid for 80% of teen births in Arizona during 2006. In 2006, hospital stays of teens with pregnancy and delivery-related diagnoses resulted in total charges to AHCCCS/Medicaid of over \$138 million dollars.
